Experiment No: 10

Experiment Name: Implementation of Round Robin scheduling algorithm

Theory:

The name of this algorithm comes from the round-robin principle, where each person gets an equal share of something in turns. It is the oldest, simplest scheduling algorithm, which is mostly used for multitasking.

In Round-robin scheduling, each ready task runs turn by turn only in a cyclic queue for a limited time slice. This algorithm also offers starvation free execution of processes.

- Round robin is a pre-emptive algorithm
- The CPU is shifted to the next process after fixed interval time, which is called time quantum/time slice.
- The process that is preempted is added to the end of the queue.
- Round robin is a hybrid model which is clock-driven
- Time slice should be minimum, which is assigned for a specific task that needs to be processed. However, it may differ OS to OS.
- It is a real time algorithm which responds to the event within a specific time limit.
- Round robin is one of the oldest, fairest, and easiest algorithm.
- Widely used scheduling method in traditional OS.

Working Process:

```
for (int i = 0; i < n; i++)
                       if (rem bt[i] > 0)
                               done = false;
                               if (rem bt[i] > quantum)
                                       t += quantum;
                                       rem_bt[i] -= quantum;
                               else
                               {
                                       t = t + rem bt[i];
                                       wt[i] = t - bt[i];
                                       rem bt[i] = 0;
                               }
                       }
               if (done == true)
               break;
       }
void findTurnAroundTime(int processes[], int n,int bt[], int wt[], int tat[])
       for (int i = 0; i < n; i++)
               tat[i] = bt[i] + wt[i];
void findavgTime(int processes[], int n, int bt[],int quantum)
{
       int wt[n], tat[n], total wt = 0, total tat = 0;
       findWaitingTime(processes, n, bt, wt, quantum);
       findTurnAroundTime(processes, n, bt, wt, tat);
       cout << "Processes "<< " Burst time "
               << " Waiting time " << " Turn around time\n";
       for (int i=0; i<n; i++)
               total wt = total wt + wt[i];
               total tat = total tat + tat[i];
               cout << " " << i+1 << "\t\t" << bt[i] <<"\t "
                       << wt[i] <<"\t\t " << tat[i] <<endl;
       }
       cout << "Average waiting time = "</pre>
```

Output:

```
Burst time Waiting time Turn around time
Processes
                10
                         13
                                         23
2
                5
                         10
                                         15
                                         21
                         13
Average waiting time = 12
Average turn around time = 19.6667
Process returned 0 (0x0)
                           execution time : 0.021 s
Press any key to continue.
```

Discussion:

This lab helps to learn Round Robin scheduling algorithm. We have implemented this algorithm using C language. In future we can solve any problem of this algorithm.
